Winter Semester 2020/21

version: 202007-022021-11-27

Overview

- Some common approaches to algorithm design
 - Revisiting recursion
 - Brute force
 - Divide and conquer
 - Greedy algorithms
 - Dynamic programming

C. Çöltekin, ISL / University of Tübingen

Winter Semester 2020/21 1 / 19

Recursion - again

linear search again

Your task from the last lecture: writing a recursive linear search.

- Recursion is relatively easy:

```
1 def r1_search(seq, val, i=0):  
2     return i  
3 else:  
4     return r1_search(seq[i:], val, i+1)
```

- And we need a base case:

```
1 def r1_search(seq, val, i=0):  
2     if not seq:  
3         return None  
4     if val == seq[0]:  
5         return i  
6     return r1_search(seq[1:], val, i+1)
```

Can we improve this?

C. Çöltekin, ISL / University of Tübingen

Winter Semester 2020/21 2 / 19

How does this recursion work

recursion trace/graph

C. Çöltekin, ISL / University of Tübingen

Winter Semester 2020/21 3 / 19

Recursion: practical issues

recursion depth and tail recursion

- Each function call requires some bookkeeping
- Compilers/interpreters allocate space on a stack for the bookkeeping for each function call
- Most environments limit the number of recursive calls: long chains of recursion is likely to be errors
- Tail recursion (e.g., our recursive search example) is easy to convert to iteration
- It is also easy to optimize, and optimized by many compilers (not by the Python interpreter)

C. Çöltekin, ISL / University of Tübingen

Winter Semester 2020/21 4 / 19

Another recursive example

an algorithm course is required to introduce Fibonacci numbers

Fibonacci numbers are defined as:

$$\begin{aligned}F_0 &= 0 \\F_1 &= 1 \\F_n &= F_{n-1} + F_{n-2} \quad \text{for } n > 1\end{aligned}$$

```
1 def fib(n):  
2     if n <= 1:  
3         return n  
4     return fib(n-2) + fib(n-1)
```

- Recursion is common in math, and maps well to the recursive algorithms
- Note that we now have binary recursion, each function call creates two calls to self
- We follow the math exactly, but is this code efficient?

C. Çöltekin, ISL / University of Tübingen

Winter Semester 2020/21 5 / 19

Visualizing binary recursion

C. Çöltekin, ISL / University of Tübingen

Winter Semester 2020/21 6 / 19

Brute force

- In some cases, we may need to enumerate all possible cases (e.g., to find the best solution)
- Common in combinatorial problems
- Often intractable, practical only for small input sizes
- It is also typically the beginning of finding a more efficient approach

C. Çöltekin, ISL / University of Tübingen

Winter Semester 2020/21 7 / 19

Brute force

example: finding all possible ways to segment a string

- Segmentation is prevalent in CL
 - Examples include finding words: tokenization (particularly for writing systems that do not use white space)
 - Finding sub-word units (e.g., morphemes, or more specialized application: compound splitting)
 - Psycholinguistics: how do people extract words from continuous speech?
- We consider the following problem:
 - Given a metric or score to determine the "best" segmentation
 - We enumerate all possible ways to segment, pick the one with the best score
- How can we enumerate all possible segmentations of a string?

C. Çöltekin, ISL / University of Tübingen

Winter Semester 2020/21 8 / 19

Segmentation

a recursive solution

```
1 def segment_r(seq):  
2     if len(seq) == 1:  
3         yield [seq]  
4     else:  
5         for seg in segment_r(seq[1:]):  
6             yield [seq[0]] + seg  
7             yield [seq[0] + seg[0]] + seg[1:]
```

- Can you think of a non-recursive solution?

C. Çöltekin, ISL / University of Tübingen

Winter Semester 2020/21 9 / 19

Enumerating segmentations

sketch of a non-recursive solution

- '1' means there is a boundary at this position
- Problem is now enumerating all possible binary strings of length $n-1$ (this is binary counting)

C. Çöltekin, ISL / University of Tübingen

Winter Semester 2020/21 10 / 19

Divide and conquer

- The general idea is dividing the problem into smaller parts until it becomes trivial to solve
- Once small parts are solved, the results are combined
- Goes very well with recursion
- We have already seen a particular flavor: binary search
- The algorithms like binary search are sometimes called *decrease and conquer*

C. Çöltekin, ISL / University of Tübingen

Winter Semester 2020/21 11 / 19

Divide and conquer

General idea

Divide and conquer

an example: nearest neighbors (only a sketch)

- Task: find the closest two points
- Direct solution:
 $20 \times 20 = 400$ comparisons¹
- Divide
- Solve separately (conquer):
 $10 \times 10 + 10 \times 10 = 200$ comparisons
- Combine: pick the minimum of the individual solutions

- Gain is higher when n is larger, and we divide further

¹Presumably, $(20 \times 19) / 2 = 190$ checks does not focus on 'order' of operations, rather than the exact numbers. And, the order of checks depends on the cases.

Divide and conquer

an example: nearest neighbors (only a sketch)

- Task: find the closest two points
- Direct solution:
 $20 \times 20 = 400$ comparisons¹
- Divide
- Solve separately (conquer):
 $10 \times 10 + 10 \times 10 = 200$ comparisons
- Combine: pick the minimum of the individual solutions

- Gain is higher when n is larger, and we divide further

¹Presumably, $(20 \times 19) / 2 = 190$ checks does not focus on 'order' of operations, rather than the exact numbers. And, the order of checks depends on the cases.

Divide and conquer

summary

- This is probably the most common example
- Divide and conquer does not always yield good results, the cost of merging should be less than the gain from division
- Many of the important algorithms fall into this category:
 - merge sort and quick sort (coming soon)
 - integer multiplication
 - matrix multiplication
 - fast Fourier transform (FFT)

Greedy algorithms

- An algorithm is greedy if it optimizes a local constraint
- For some problems, greedy algorithms result in correct solutions
- In others they may result in 'good enough' solutions
- If they work, they are efficient
- An important class of graph algorithms fall into this category (e.g., finding shortest paths, scheduling)

Greedy algorithms

a simple example: 'change making'

- We want to produce minimum number of coins for a particular sum s
 - Pick the largest coin $c \leq s$
 - set $s = s - c$
 - repeat 1 & 2 until $s = 0$
- Is this algorithm correct?
- Think about coins of 10, 30, 40 and apply the algorithm for the sum value of 60
- Is it correct if the coin values were limited Euro coins?

Dynamic programming

- Dynamic programming is a method to save earlier results to reduce computation
- It is sometimes called memoization (it is not a typo)
- Again, a large number of algorithms we use fall into this category, including common parsing algorithms

Dynamic programming

example: Fibonacci

```

def memofib(n, memo = {0: 0, 1: 1}):
    if n not in memo:
        memo[n] = memofib(n-1) + memofib(n-2)
    return memo[n]
  
```

- We save the results calculated in a dictionary,
- if the result is already in the dictionary, we return without recursion
- Otherwise we calculate recursively as before
- The difference is big, but there is also a 'neater' solution without (explicit) memoization

Summary

- We saw a few general approaches to (efficient) algorithm design
- Designing algorithms is not a mechanical procedure: it requires creativity
- There are other common patterns, including
 - Backtracking, Branch-and-bound
 - Randomized algorithms
 - Distributed algorithms (sometimes called swarm optimization)
 - Transformation
- Designing algorithms is difficult but analyzing them is even more difficult (next topic)

Next:

- Analysis of algorithms
- Reading: textbook (Goodrich, Tamassia, and Goldwasser 2013) chapter 3

Linear search

a little bit of optimization

```

def rl_search(seq, val, i=0):
    if not seq:
        return None
    if val == seq[i]:
        return i
    else:
        return rl_search(seq[i+1:], val, i+1)
  
```

```

def rl_search3(seq, val, i=0):
    if i > len(seq):
        return None
    if val == seq[i]:
        return i
    else:
        return rl_search3(seq, val, i+1)
  
```

Which one is faster, and why?

Better solutions for Fibonacci numbers

```

def fib0(n):
    if n <= 1:
        return (n, 0)
    a, b = fib0(n-1)
    return (a+b, a)
  
```

```

def fib1(n):
    if n <= 1:
        return a
    a, b = 0, 1
    for i in range(0, n):
        a, b = b, a+b
    return a
  
```

Which one is faster/better?

```

def segment_r(seq):
    segs = []
    if len(seq) == 1:
        return [seq]
    for seg in segment_r(seq[1:]):
        segs.append([seq[0]] + seg)
        segs.append([seq[0] + seg[0]] + seg[1:])
    return segs
  
```
