# Finding patterns in a string

- Finding a pattern in a larger text is a common problem in many applications
- Typical example is searching in a text editor or word processor
- There are many more:
  - DNA sequencing / bioinformatics
  - Plagiarism detection
  - Search engines / information retrieval
  - Spell checking
  - ...

# Types of problems

- The efficiency and usability of algorithms depend on some properties of the problem
- Typical applications are based on finding multiple occurrences of a single pattern in a text, where the pattern is much shorter than the pattern
- The efficiency of the algorithms may depend on the
  - relative size of the pattern
  - expected number of repetitions
  - size of the alphabet
  - whether the pattern is used once or many times
- Another related problem is searching for multiple patterns at once
- In some cases, fuzzy / approximate search may be required
- In some applications, preprocessing (indexing) the text to be searched may be beneficial

# Problem definition

and some terminology

- We want to find all occurrences of pattern  $p$  (length  $m$ ) in text  $t$  (length  $n$ )
- The characters in both  $t$  and  $p$  are from an alphabet  $\Sigma$ , in the example  $\Sigma = \{A, C, G, T\}$
- The size of the alphabet ( $q$ ) is often an important factor
- $p$  occurs in  $t$  with shift  $s$  if  $p[0 : m] == t[s : s + m]$ , we have a match at  $s = 3$  in the example
- A string  $x$  is a prefix of string  $y$ , if  $y = xw$  for a possibly empty string  $w$
- A string  $x$  is a suffix of string  $y$ , if  $y = wx$  for a possibly empty string  $w$

# Brute-force string search

- Start from the beginning, of  $i = 0$  and  $j = 0$ 
  - if  $j == m$ , announce success with  $s = i$
  - if  $t[i] == p[j]$ : shift  $p$  ( $i+ = 1, j = 0$ )
  - otherwise: compare the next character ( $i+ = 1, j+ = 1$ , repeat)

# Brute-force string search

- Start from the beginning, of  $i = 0$  and  $j = 0$ 
  - if  $j == m$ , announce success with  $s = i$
  - if  $t[i] == p[j]$ : shift  $p$  ( $i+ = 1, j = 0$ )
  - otherwise: compare the next character ( $i+ = 1, j+ = 1$ , repeat)

# Brute-force string search

- Start from the beginning, of  $i = 0$  and  $j = 0$ 
  - if  $j == m$ , announce success with  $s = i$
  - if  $t[i] == p[j]$ : shift  $p$  ( $i+ = 1, j = 0$ )
  - otherwise: compare the next character ( $i+ = 1, j+ = 1$ , repeat)

# Brute-force string search

- Start from the beginning, of  $i = 0$  and  $j = 0$ 
  - if  $j == m$ , announce success with  $s = i$
  - if  $t[i] == p[j]$ : shift  $p$  ( $i+ = 1, j = 0$ )
  - otherwise: compare the next character ( $i+ = 1, j+ = 1$ , repeat)

# Brute-force string search

- Start from the beginning, of  $i = 0$  and  $j = 0$ 
  - if  $j == m$ , announce success with  $s = i$
  - if  $t[i] == p[j]$ : shift  $p$  ( $i+ = 1, j = 0$ )
  - otherwise: compare the next character ( $i+ = 1, j+ = 1$ , repeat)

# Brute-force string search

- Start from the beginning, of  $i = 0$  and  $j = 0$ 
  - if  $j == m$ , announce success with  $s = i$
  - if  $t[i] == p[j]$ : shift  $p$  ( $i+ = 1, j = 0$ )
  - otherwise: compare the next character ( $i+ = 1, j+ = 1$ , repeat)

# Brute-force string search

- Start from the beginning, of  $i = 0$  and  $j = 0$ 
  - if  $j == m$ , announce success with  $s = i$
  - if  $t[i] == p[j]$ : shift  $p$  ( $i+ = 1, j = 0$ )
  - otherwise: compare the next character ( $i+ = 1, j+ = 1$ , repeat)

# Brute-force string search

- Start from the beginning, of  $i = 0$  and  $j = 0$ 
  - if  $j == m$ , announce success with  $s = i$
  - if  $t[i] == p[j]$ : shift  $p$  ( $i+ = 1, j = 0$ )
  - otherwise: compare the next character ( $i+ = 1, j+ = 1$ , repeat)

# Brute-force string search

- Start from the beginning, of  $i = 0$  and  $j = 0$ 
  - if  $j == m$ , announce success with  $s = i$
  - if  $t[i] == p[j]$ : shift  $p$  ( $i+ = 1, j = 0$ )

# Brute-force approach: worst case

# Brute-force approach: worst case

## Brute-force approach: worst case

- Worst-case complexity of the method is  $O(nm)$
- Crucially, most of the comparisons are redundant
  - for  $i > 0$  and any comparison with  $j = 0, 1, 2$ , we already inspected corresponding  $i$  values
- The main idea for more advanced algorithms is to avoid this unnecessary comparisons

# Boyer-Moore algorithm

slightly simplified version

- The main idea is to start comparing from the end of  $p$
- If  $t[i]$  does not occur in  $p$ , shift  $m$  steps
- Otherwise, align the last occurrence of  $t[i]$  in  $p$  with  $t[i]$

# Boyer-Moore algorithm

slightly simplified version

- The main idea is to start comparing from the end of  $p$
- If  $t[i]$  does not occur in  $p$ , shift  $m$  steps
- Otherwise, align the last occurrence of  $t[i]$  in  $p$  with  $t[i]$

# Boyer-Moore algorithm

slightly simplified version

- The main idea is to start comparing from the end of  $p$
- If  $t[i]$  does not occur in  $p$ , shift  $m$  steps
- Otherwise, align the last occurrence of  $t[i]$  in  $p$  with  $t[i]$

# Boyer-Moore algorithm

slightly simplified version

- The main idea is to start comparing from the end of  $p$
- If  $t[i]$  does not occur in  $p$ , shift  $m$  steps
- Otherwise, align the last occurrence of  $t[i]$  in  $p$  with  $t[i]$

# Boyer-Moore algorithm

- The main idea is to start comparing from the end of  $p$
- If  $t[i]$  does not occur in  $p$ , shift  $m$  steps
- Otherwise, align the last occurrence of  $t[i]$  in  $p$  with  $t[i]$

# Boyer-Moore algorithm

slightly simplified version

- The main idea is to start comparing from the end of  $p$
- If  $t[i]$  does not occur in  $p$ , shift  $m$  steps
- Otherwise, align the last occurrence of  $t[i]$  in  $p$  with  $t[i]$

# Boyer-Moore algorithm

slightly simplified version

- The main idea is to start comparing from the end of  $p$
- If  $t[i]$  does not occur in  $p$ , shift  $m$  steps
- Otherwise, align the last occurrence of  $t[i]$  in  $p$  with  $t[i]$

# Boyer-Moore algorithm

## implementation and analysis

- On average the algorithm performs better than brute-force
- In worst case the complexity of the algorithm is  $O(nm)$ , example:  
 $t = aaa \dots a, p = baa \dots a$
- Faster versions exist ( $O(n + m + q)$ )

```

last = {}
for j in range(m):
    last[P[j]] = j
i, j = m-1, m-1
while i < n:
    if T[i] == P[j]:
        if j == 0:
            return i
        else:
            i -= 1
            j -= 1
    else:
        k = last.get(T[i], -1)
        i += m + min(j, k+1)
        j = m - 1
return None

```

# A quick introduction to FSA

- Another efficient way to search a string is building a finite state automaton for the pattern
- An FSA is a directed graph where edges have labels
- One of the states is the *initial state*
- Some states are accepting states
- We will study FSA more in-depth soon

# An FSA for the pattern ACGAC

- Start at state 0, switch states based on the input
- All unspecified transitions go to state 0
- When at the accepting state, announce success

# FSA pattern matching

# FSA for string matching

## how to build the automaton

- An FSA results in  $O(n)$  time matching, however, we need to first build the automaton
- At any state of the automaton, we want to know which state to go for the failing matches
- Given substring  $s$  recognized by a state and a non-matching input symbol  $a$ , we want to find the longest prefix of  $s$  such that it is also a suffix of  $sa$
- A naive attempt results in  $O(qm^3)$  time for building the automaton (where  $q$  is the size of the alphabet  $m$  is the length of the pattern)
- If stored in a matrix, the space requirement is  $O(m^2)$
- Better (faster) algorithms exist for construction these automaton (we will cover some later in this course)

# Knuth-Morris-Pratt (KMP) algorithm

- The KMP algorithm is probably the most popular algorithm for string matching
- The idea is similar to the FSA approach: on failure, continue comparing from the longest matched prefix so far
- However, we rely on a simpler data structure (a function/table that tells us where to back up)
- Construction of the table is also faster

# KMP algorithm

## demonstration

- In case of a match, increment both  $i$  and  $j$
- On failure, or at the end of the pattern, decide which new  $p[j]$  compare with  $t[i]$  based on a function  $f$
- $f[j - 1]$  tells which  $j$  value to resume the comparisons from

# KMP algorithm

## demonstration

- In case of a match, increment both  $i$  and  $j$
- On failure, or at the end of the pattern, decide which new  $p[j]$  compare with  $t[i]$  based on a function  $f$

# Rabin-Karp algorithm

- Rabin-Karp string matching algorithm is another interesting algorithm
- The idea is instead of matching the string itself, matching the hash of it (based on a hash function)
- If a match found, we need to verify – the match may be because of a hash collision
- Otherwise, the algorithm makes a single comparison for each position in the text
- However, a hash should be computed for each position (with size  $m$ )
- Rolling hash functions avoid this complication

# Rabin-Karp string matching

demonstration with additive hashing

$t$ :

7	1	3	6	7	4	3	8	5	7	9	4	3	9
---	---	---	---	---	---	---	---	---	---	---	---	---	---

$$h = 39$$

$p$ :

4	3	8	5	7	9	4	3
---	---	---	---	---	---	---	---

$$h(p) = 43$$

- A rolling hash function changes the hash value only based on the item coming in and going out of the window
- To reduce collisions, better rolling-hash functions (e.g., polynomial hash functions) can also be used

# Summary

- String matching is an important problem with wide range of applications
- The choice of algorithm largely depends on the problem
- We will revisit the problem on regular expressions and finite-state automata
- Reading: Goodrich, Tamassia, and Goldwasser (2013, chapter 13)

Next:

- Algorithms on strings: edit distance / alignment, tries
- Reading: Goodrich, Tamassia, and Goldwasser (2013, chapter 13), Jurafsky and Martin (2009, section 3.11, or 2.5 in online draft)
